1 30 **ABSTRACT**

2
3
4 31 Bigels are biphasic systems produced with an organogel (or oleogel) and a hydrogel
5
6
7 32 mixed together at high shear rates. These systems are promising for different uses,
8
9 33 among them the formulation of new cosmetic matrices for cosmetic agents delivery is
10
11 34 under investigation. In the present paper, a common cosmetic formulation for skin care
12
13 35 was enriched with increasing fractions of monoglycerides of fatty acids/olive oil
14
15 36 organogels, in order to understand the rheology and the microstructure of these systems.
16
17 37 Small Amplitude Oscillation Tests, NMR-self diffusion analysis, contrast phase
18
19 38 microscopy and electric conductivity confirmed that the addition of the organogel
20
21 39 caused a microstructural change of the starting material, which turned from O/W to a
22
23 40 more complex system where, probably, a matrix-in-matrix structure is present at the
24
25 41 highest fractions of added organogel.

1 45 **1. INTRODUCTION**

2
3
4 46 Structured two-phase systems are used in a great variety of industrial fields (food,
5
6
7 47 cosmetic, pharmaceutical) owing to their peculiar properties coming from the presence
8
9
10 48 of two different phases (usually a lipophilic and a hydrophilic ones) and to the
11
12 49 possibility of finely tuning the consistency of the final product by modifying both the
13
14 50 consistency of the single phases and their relative amount. Different systems can be
15
16
17 51 obtained, according to the structure level of the single phases. When only the
18
19 52 continuous phase is structured these systems are, usually, named “emulgels” or “filled
20
21 53 gels” to take into account both the emulsion-like behaviour of these materials and the
22
23
24 54 relevant role played by the solid-like dispersing phase [1-5]. When only the internal
25
26 55 phase is gelled they behave mainly like suspensions made of soft (and deformable)
27
28
29 56 particles with a maximum packing fraction according to the particle rheological
30
31 57 properties [6]. When both phases are structured a more complex behaviour, according to
32
33
34 58 the properties of both phases, is observed and the systems can be classified as “bigels”
35
36 59 or “biphasic gels” [5, 7, 8]. Emulgels and bigels are particularly interesting owing to
37
38
39 60 their potential use in the cosmetic and pharmaceutical area because they can merge the
40
41 61 advantages of emulsions and gels (both hydrogels and organogels) to control drug
42
43
44 62 delivery for topical and transdermal use [5].

45
46
47 63 In the case of cosmetic formulations, in particular face and body/skin care creams, all
48
49 64 the mechanical and textural properties requested by consumers should be guaranteed by
50
51
52 65 manufacturers. In the light of this, these materials have to be humectant, emollient, skin
53
54 66 softeners and, often, a carrier for active ingredients (antioxidants, vitamins, colouring
55
56
57 67 agents or pigments) which should permeate through the skin [9]. In addition, in order to

1 68 meet consumers' preference they should ensure specific rheological properties i.e.
2
3 69 smoothness, thickness but also spreadability, often influenced by the texture of the
4
5
6 70 product [10]. Another very important characteristic of cosmetic preparations is high
7
8 71 storage stability, which has to be maintained over several months or, in some cases,
9
10
11 72 years [11]. In fact, cosmetic products such as lotions or creams are formed by two
12
13 73 immiscible phases, one polar (the aqueous phase) and the other one nonpolar (the oil
14
15 74 phase). According to their different physical and chemical properties, biphasic systems
16
17
18 75 can incur phases instability such as creaming, coalescence, flocculation, sedimentation,
19
20
21 76 Ostwald ripening, and phase inversion [12]. The modification of the mechanical
22
23 77 properties of both the aqueous and the oil phase (by thickening and/or gelation) is,
24
25 78 therefore, necessary for improving the spreadability and the smoothness of the cream
26
27
28 79 and, on the other hand, for enhancing its storage stability. In fact, owing to the difficulty
29
30
31 80 of droplets to move easily through the three-dimensional network of the gel, they cannot
32
33 81 aggregate or flocculate, stabilizing the system.

34
35
36 82 Bigels are interesting innovative two-phase systems that have been recently proposed
37
38 83 [5, 13] as structured systems able to properly control the delivery of active ingredients;
39
40
41 84 they possess the advantages typical of both gels, such as: ease of preparation, absence of
42
43 85 huge quantities of surfactants sometimes toxic, and possible controlled delivery of both
44
45
46 86 lipophilic and hydrophilic active agents [5, 8]. Looking at these interesting properties, a
47
48 87 growing number of authors is studying bigels as active agent carriers. Rhee et al,
49
50
51 88 proposed bigels for ketoprofen transdermal administration [13]; Behera et al.
52
53 89 investigated the physical properties of bigels made of synthetic polymers hydrogels
54
55
56 90 (PVA and PVP), and sunflower oil and span 40 oleogels, for the delivery of
57
58 91 metronidazole [14]; metronidazole was also added to carbopol hydrogel/Sorbitan

1 92 monostearate-sesam oil organogel studied by Singh et al., [15], and the controlled
2
3 93 delivery of ciprofloxacin was studied, again by Singh et al. [8], with a guar gum
4
5
6 94 hydrogel and sorbitan monostearate-sesame oil based organogel.
7
8

9 95 All the cited papers discuss the mechanical and microscopic characteristics of bigels.
10
11 96 Singh et al. [8] studied the microscopic morphology of samples and the rheological
12
13 97 properties in terms of viscosities and ‘creep and recovery’ tests; the same group carried
14
15 98 out also small amplitude oscillation tests for similar systems [7] and fluorescent
16
17 99 microphotographs were moreover taken in their work based on carbopol-based bigels
20
21 100 [15]. Texture analysis (creep recovery tests) were also taken by Satapathy et al. [4] in
22
23 101 their study comparing gelatin-based hydrogels, emulsion hydrogels, and bigels, while
24
25 102 Rehman et al. [16] characterized the polarized optical microscopy, viscosity and texture
26
27 103 properties of polymer-fish oil bigels. Finally, fluorescence microscopy and rheological
28
29 104 tests (texture analysis, viscosity, stickiness and stress relaxation) was investigated by
30
31 105 Behera et al. [14]. Apart from these techniques of investigation, no other works were
32
33 106 published dealing with the microstructure of the systems and further investigations can
34
35 107 be very useful to better understanding structure and behaviour of these materials.
36
37
38
39
40
41

42 108 In the present paper, structured two-phase systems (bigels) were prepared and
43
44 109 investigated by using rheological methods and Nuclear Magnetic Resonance (NMR)
45
46 110 techniques aiming at better understanding the relationship between rheological
47
48 111 properties and microstructure and to describe the effects of the structured dispersed
49
50 112 phase on final product behaviour. In fact, different fractions of olive oil organogels were
51
52 113 added to a typical basis for oil-in-water cosmetic creams, and different techniques were
53
54
55
56
57
58
59
60
61
62
63
64
65

1 114 used to study the effect of this addition on the rheological and microstructural properties
2
3
4 115 of the systems.
5
6
7 116 Colloidal suspensions characterisation by using Nuclear Magnetic Resonance (NMR)
8
9 117 techniques is a vast and even expanding scientific endeavour [17, 18]. Owing to its non-
10
11 118 invasive nature, and ability to probe structures over a broad range of length scales,
12
13 119 NMR has established itself as a tool for the structural characterisation of anisotropic
14
15 120 domain sizes in liquid crystals [19], fluctuations in ordered lamellar phases under weak
16
17 121 shear [20] and the sizing of shear-induced multi-lamellar vesicles [21, 22]. It was also
18
19 122 used for cosmetic emulsions [23] and food emulsions [24-27] characterisation. With
20
21 123 respect to two-phase systems, NMR offers a variety of unique insights into both
22
23 124 molecular orientation and transport kinetics within the various phases. One of the major
24
25 125 contributions arguably is the possibility of easily deciding whether a given emulsion is
26
27 126 of the discrete oil-in-water (O/W), discrete water-in-oil (W/O), or bicontinuous type
28
29 127 from the oil and water self-diffusion coefficients [28]. Moreover, it is used to provide
30
31 128 the droplet size distribution (DSD) of the emulsions [17, 27] and even long-range order
32
33 129 of droplets in structured emulsions [24, 29, 30]. Even though a vast literature is
34
35 130 available on emulsion studies, to the best of our knowledge, there is no available work
36
37 131 on NMR characterisation of bigels. Starting from these considerations it has been
38
39 132 considered interesting to use this non-invasive powerful technique to investigate bigel
40
41 133 evolution with increasing oleogel content. Moreover, the characterisation was
42
43 134 completed by using phase contrast microscopy and electrical conductivity determination
44
45 135 to evaluate potential changes in relative distribution of the phases.

63
64
65

1 136 Bigels investigated in this paper are based on sulphurous hyperthermal water, and olive
2
3 137 oil. Hyperthermal water is well-known because it exerts anti-inflammatory, anti-
4
5 138 pruriginous, keratoplastic and keratolytic effects [31]; olive oil, used alone or as an
6
7 139 ingredient in dermo-cosmetology and topical applications, shows therapeutic effects
8
9 140 (e.g., anti-inflammatory, anti-neoplastic, and anti-aging), and prevents skin alterations
10
11 141 physiologically caused by time and different external irritating factors [32].
12
13
14
15

16 142 The aqueous phase was structured by using a common hydrocolloid, acting as gelling
17
18 143 agent and thickener, such as potato starch. Olive oil was organogelled with a mixture of
19
20 144 monoglycerides of fatty acids. Previous studies were carried out to investigate the main
21
22 145 characteristics of different kinds of organogels [33, 34], and in particular,
23
24 146 monoglycerides/olive oil organogels alone [34, 35], and mixed with other semisolid
25
26 147 matrices [36] were investigated. The organogel was added to the base cream at room
27
28 148 temperature, and the bigel preparation resulted easy, giving very smooth and
29
30 149 homogeneous materials.
31
32
33
34
35
36

37 150

40 151 **2. MATERIALS AND METHODS**

43 152 **2.1 Materials**

44 153 Bigels were produced by adding different amounts of an olive oil/monoglycerides of
45
46 154 fatty acids organogel to a typical cosmetic oil-in-water structured emulsion basis for
47
48 155 skin care, named E0. A schematic description of bigel production is sketched in Fig. 1.
49
50
51
52
53

54 156 *2.1.1 Cosmetic base cream preparation*

1 157 Sample E0 (Table 1) is a newly formulated O/W emulsion (base) which was found
2
3 158 stable after evaluating for pH, electrical conductivity, centrifugation, phase separation,
4
5 159 temperature stability tests (data not shown). It was prepared according to a commercial
6
7
8 160 formulation kindly suggested by SA.TE.CA. S.r.l, a local company that produces skin
9
10
11 161 care products with sulphurous hyperthermal water. All ingredients adopted for E0
12
13 162 preparation were supplied by A.C.E.F. (Italy) except for modified potato starch (from
14
15 163 Maycos, Italy) and essential oils (from Muller & Koster, Italy).

16 164 For emulsion preparation, both the oil and the aqueous phases were separately heated up
17
18
19 165 to 70°C, and the emulsions were prepared by the addition of oily phase to the aqueous
20
21
22 166 phase in a standard turbo-emulsifier for 20 minutes at 900 rpm (CCT, Timatic, Italy).
23
24
25 167 The mixing operation continued at different speeds at 35°C and finally essential oils
26
27
28 168 were also added to the mixture.

29
30
31
32 169 This system can be considered as an “emulgel” or a “filled gel”, according to the
33
34 170 classification previously described, because the dispersing water phase is structured by
35
36
37 171 potato starch gelatinisation that occurs when potato starch is heated in the presence of
38
39 172 water at temperatures ranging, approximately, between 60°C and 70°C [37].
40
41

42 173 *2.1.2 Organogel preparation*

43
44
45 174 Organogel was prepared with an extra virgin olive oil (Gabro, Italy) as the solvent, and
46
47
48 175 with a mixture monoglycerides of fatty acids (Myverol 18 04 K, Kerry Group, Ireland,
49
50
51 176 referred to as Myverol throughout the paper) [35], antioxidant agents (α -tocopherol and
52
53 177 ascorbyl palmitate, A.C.E.F., Italy) and a certain amount of *algae*, an extract of algal
54
55
56 178 microflora, kindly supplied by SA.TE.CA. S.r.l. Algal cultures, mainly consisting of
57
58 179 *cyanobacteria* and *sulfobacteria*, were grown into a “*sulphuretum*” made of shallow-

1 180 water hyperthermal tubs (46° C). The products of their metabolism constitute an organic
2
3 181 matrix containing significant amounts of unsaponifiable lipids, carotenoids and
4
5 182 retinoids that possess some antioxidant function and anti-inflammatory properties [38].
6
7
8 183 The exact composition of the organogel is listed in Table 2. The Myverol amount is
9
10 184 intermediate between the values of samples previously investigated in the literature
11
12 185 [39], and therefore, its rheological properties should be intermediate as well. It was
13
14 186 produced, following a procedure already adopted, in the literature, for organogel
15
16 187 preparation [1]: the oil, with α -tocopherol, *algae* and ascorbyl palmitate, was mixed
17
18 188 using a laboratory stirrer (RW 20, IKA, Germany) and it was heated up to 70°C in a
19
20 189 water bath thermostated by a plate heater (Jolly 2, Falc Instruments, Italy). Then the
21
22 190 organogelator was added and the mixture was stirred for 15 minutes. Finally the system
23
24 191 was gently stirred and cooled down with a fast cooling rate quenching it in a
25
26 192 thermostatic cold bath (at 0 °C) down to the final temperature of 20 °C. In this case the
27
28 193 oil phase was poured into a round aluminium vessel, where the final thickness of the
29
30 194 cold hard fatty phase reached a maximum value of about 1 cm, in order to obtain a fast
31
32 195 and, approximately, uniform cooling [1].
33
34
35
36
37
38
39
40

41 196 *2.1.3 Bigel preparation*

42
43
44 197 The base emulgel (sample E0) was modified by introducing the organogel and varying
45
46 198 the aqueous phase/oil phase ratio, according to Table 3. In order to promote the
47
48 199 organogel dispersion within the emulgel E0, vegetable glycerol (A.C.E.F., Italy) was
49
50 200 also added, according to the company empirical knowledge and as suggested by the
51
52 201 literature [40], in a total amount of 0.5 g of glycerol per 100 grams of final samples for
53
54 202 E5, and 3.5 grams per 100 grams of final sample for the other emulsions. Samples E5-
55
56 203 E25 were prepared by mixing sample E0 with the right amount of organogel and
57
58
59
60
61
62
63
64
65

1 204 glycerol at room temperature, by using a commercial blender (Minipimer MQ100,
2
3 205 Braun, Germany) working at 700 rpm for 5 min. In this way, a bigel made by a starch
4
5 206 hydrogel and a Myverol organogel was prepared. Anyway, it is worth noting that the
6
7
8 207 investigated system is more complex than a “common” bigel because also oil droplets,
9
10
11 208 coming from the starting emulgel, are still present in the final material.

12
13
14 209

17 210 **2.2 Rheological characterisation**

18
19
20
21 211 All samples were investigated with a rheological analysis aimed at characterising the
22
23 212 mechanical properties and their possible relationship with the bigels microstructure.

24
25
26 213 Small Amplitude Oscillation Tests (SAOTs) were performed in the linear viscoelastic
27
28
29 214 region. In particular, frequency sweep tests at 25°C and 36°C (with the aim of
30
31 215 simulating the typical temperature of human body) were carried out in the range 0.1 - 10
32
33
34 216 Hz. Moreover, temperature ramp tests were performed at the fixed frequency of
35
36 217 oscillation of 1 Hz, increasing temperature from 25°C up to 70°C with a heating rate of
37
38
39 218 1°C/min. Both tests were performed on a stress control rheometer DSR-500
40
41 219 (Rheometric Scientific, USA) equipped with a parallel plate geometry ($\phi=25$ mm, gap
42
43 220 2.0 ± 0.2 mm). Temperature was controlled with a Peltier system acting under the lower
44
45
46 221 plate of the rheometer.

47
48
49 222 From a rheological point of view the investigated systems can be considered as weakly
50
51
52 223 structured materials with rheological “units” that are connected by weak bonds and
53
54 224 build a three-dimensional network [1, 41]. Being the complex modulus G^* a
55
56
57 225 combination of the storage modulus G' and the dissipative one G'' , as shown in eq. (1),
58
59

1 226 according to the model, data can be fitted using a two-parameter power law equation

2
3
4 227 [41]:

5
6
7
8 228
$$G^*(\omega) = \sqrt{(G')^2 + (G'')^2} = A \cdot \omega^{\frac{1}{z}}$$
 (1)

9
10
11 229 where the parameter A is the “strength of interactions” or the “strength of the gel” and is

12
13
14 230 related to the strength of the interactions among the rheological units, whereas z is the

15
16
17 231 “coordination number” or the “network extension” and it is related to the number of

18
19 232 interacting rheological units within the 3-D network [41]. When A increases, the

20
21
22 233 interaction forces within the network increase, whereas a high z value indicates a large

23
24 234 number of interacting units cooperating and increasing the network connectivity making

25
26 235 the system more “structured”; therefore z by extension, could be considered a

27
28
29 236 “structuration degree”. Data fitting is carried out through Table Curve 2D Software

30
31 237 (Jandel Scientific, USA).

32
33
34
35 238

36
37
38 239 **2.3 Electric conductivity**

39
40
41 240 The electric conductivity (κ) was measured by means of an Orion model 120

42
43
44 241 Microprocessor Conductivity Meter fitted with an electrode having a cell constant of

45
46 242 1.02 cm^{-1} . The temperature was kept at $25.0 \pm 0.1^\circ\text{C}$ and was maintained by a Lauda

47
48
49 243 M-20 thermostat. The error limit of conductance measurements was $\pm 0.02 \mu\text{S cm}^{-1}$.

50
51
52 244

53
54
55 245 **2.4 ^1H Self-Diffusion NMR**

1 246 Self-diffusion coefficients were measured by a Diff30 Z probe with a maximum
 2
 3 247 gradient strength of 1200 G·cm⁻¹. They were determined on a Bruker Avance 300
 4
 5 248 spectrometer operating at 300.0 MHz on ¹H nuclei. The diffusion experiments were
 6
 7
 8 249 performed using the longitudinal eddy current delay - pulse gradient stimulated-echo
 9
 10 250 (LED-PGSTE) [42] sequence. LED is a method to avoid eddy current artefacts placing
 11
 12 251 an eddy current delay after the application of a gradient pulse. In this case a delay of 6
 13
 14
 15 252 ms was used for all experiments. In the LED-PGSTE sequence, as well as in the PGSTE
 16
 17 253 a pair of trapezoidal narrow magnetic field gradient pulses with amplitude *g* and
 18
 19 254 duration δ encode for spin displacement over a controlled observation time Δ . By
 20
 21 255 applying the pulsed magnetic field gradients along the z-direction the corresponding
 22
 23 256 diffusion coefficient can be determined. The experimental conditions to measure water
 24
 25 257 self-diffusion coefficients were preliminary optimised for these sample and they are: Δ
 26
 27 258 = 140 ms, $\delta = 2$ ms and *g* were varied from 1 to 50 G·cm⁻¹ in 16 gradient steps, while
 28
 29 259 for oil self-diffusion $\Delta = 30$ ms, $\delta = 2$ ms and *g* were varied from 10 to 400 G·cm⁻¹ in 16
 30
 31 260 gradient steps.

32
 33
 34
 35
 36
 37
 38 261 The spin-echo decays were analyzed according to Stejskal and Tanner [43], however
 39
 40 262 some of the acquired data did not fit to a mono-exponential decay, consequently the
 41
 42 263 following equation was used to fit the experimental data

$$43
 44
 45
 46
 47 264 \quad I = I_0 \sum_{n=1}^k f^n e^{\left[-D_n(\gamma\delta g)^2\left(\Delta-\frac{\delta}{3}\right)\right]} \quad (2)$$

48
 49
 50
 51
 52 265 Where *I* and *I*₀ represent the water resonance peak intensity in the presence and absence
 53
 54 266 of field gradients and γ is the proton gyro-magnetic ratio, while *f*^{*n*} is the weight of the *n*-
 55
 56 267 th diffusion coefficient *D*_{*n*} (i.e. the fraction of molecules with that coefficient). For

1 268 water self-diffusion experiments k was equal to 2, while for the oil self-diffusion a
2
3 269 mono-exponential decay was fitting well the data. All measurements were performed at
4
5
6 270 25.0 ± 0.5 °C., which was controlled using the standard variable temperature unit of
7
8 271 Bruker spectrometers based on an air-flow system.

12

13 14 15 273 **2.5 Contrast phase Microscopy Tests** 16

17
18 274 The inner microstructure of the emulsions was investigated with optical microscopy.
19
20 275 The microphotographs were taken using a contrast phase microscopy (MX5300H,
21
22
23 276 MEIJI, Japan) equipped with phase contrast objective 40X. Samples were diluted to
24
25 277 reduce both the potential presence of droplets aggregates (and therefore making
26
27
28 278 photomicrographs more easily analysable) and the sample opacity [44]. All samples
29
30 279 were placed onto a glass slide inside a cover-imaging chamber (Sigma Aldrich,
31
32
33 280 Germany) on which a cover slide was put. The cover chamber forms a sealed volume
34
35 281 for thick and free-floating specimens.
36

37
38
39 282
40

41 42 283 **3. RESULTS AND DISCUSSION** 43

44 45 284 **3.1 Rheological characterisation** 46

47
48 285 The rheological characteristics of the systems investigated in the present work are
49
50
51 286 similar to those of solid-like weakly structured gel creams commonly used in cosmetic
52
53 287 or pharmaceutical applications. In a frequency sweep test, at both the investigated
54
55
56 288 temperatures of analysis, complex modulus is slightly dependent on the frequency of
57
58 289 oscillation, and loss tangent is lower than unity in the whole range of investigated
59

1 290 frequency (Fig. 2). According to weak gel model, parameters A and z were evaluated
2
3 291 (coefficient of determination R^2 for all fittings ranges between 0.92 and 0.99) for each
4
5 292 emulsion and at both temperatures of analysis (i.e. 25 and 36°C, see Fig. 3). It is worth
6
7
8 293 noticing that the network strength, described by parameter A , increases with the
9
10 294 organogel content, or, by extension, with oil phase, up to sample E10. When the oil
11
12
13 295 phase content is further increased, a first decrease of A is evidenced, for sample E15,
14
15 296 and a following new increase is observed in samples E20 and E25.

16
17
18 297 On the contrary, the network extension follows an opposite trend: structuration seems to
19
20
21 298 decrease starting from E0 up to E10 (see parameter z), then it increases in sample E15
22
23 299 and afterwards it decreases again up to sample E25. Similar behaviours are observed at
24
25
26 300 both 25°C and 36°C, even though the trend of the structuration degree (parameter z) is
27
28 301 less evident at 36°C with respect to lower temperature data.

29
30
31 302 The observed trend is quite unexpected because with increasing organogel content (and
32
33 303 therefore with dispersed structured fraction) an increase in moduli (and therefore in A)
34
35 304 was expected.

36
37
38 305 On the other hand it is known that in the case of O/W emulsions, the increase of the
39
40
41 306 dispersed phase fraction is responsible for the increase of emulsions viscosity up to a
42
43 307 maximum oil fraction [45]. Exceeding this value, a phase inversion can occur, and, at
44
45
46 308 first, viscosity decreases, increasing again if further fractions of oil are added to the
47
48 309 system. As an example, Abdurahman et al. [46] studied the case of crude oil in water
49
50
51 310 emulsions, finding that a slope change in the curve of emulsions viscosity *versus* oil
52
53 311 fraction identified a phase inversion of the emulsion. It is obvious that systems shown in
54
55 312 the present paper are different and more complex than the cited crude oil emulsions,
56
57
58
59
60
61
62
63
64
65

1 313 also because the rheological properties of both the oil and aqueous phase are different.
2
3 314 Anyway, the change in viscosity, as function of oil fraction, observed in the present
4
5
6 315 work is very similar to that observed in the cited paper suggesting that a structural
7
8 316 change in biphasic microstructure could occur between samples E10 and E20, which
9
10
11 317 can be generally attributed to either the inversion of phases or the formation of
12
13 318 bicontinuous bigels.
14
15
16 319 Nevertheless, the rheological characterisation, alone, is not able to give more detailed
17
18
19 320 information about microstructure, therefore different techniques were used in order to
20
21 321 better understand the potential changes.
22
23
24 322 The addition of an organogel within the starting emulsion matrix changes also the
25
26
27 323 stability of the system. Recently, temperature ramp tests were proposed as a valid
28
29
30 324 method to simulate the forced accelerated destabilisation of cosmetic emulsions, if
31
32 325 compared with the common accelerated aging tests [2], and a constant trend of both
33
34 326 moduli with temperature can be attributed to a more stable system. Fig. 4 shows the
35
36
37 327 temperature ramp tests in terms of complex moduli and loss tangents *versus* temperature
38
39 328 of sample E0 compared with E25. Both samples evidence an almost constant trend of
40
41
42 329 complex modulus at low temperature, followed by a more pronounced reduction of G^*
43
44 330 starting at approximately 45°C. On the other hand, the loss tangent slightly increases but
45
46
47 331 it is always lower than unity evidencing a prevalent solid-like behaviour of the
48
49 332 materials. This rheological behaviour can be attributed to the presence of the starch gel
50
51
52 333 that is not thermoreversible [47] and on heating becomes only softer without melting.
53
54 334 As a consequence, it can be speculated that the increase in temperature is not causing
55
56 335 the rupture of the two-phase system (that is observed when the structured dispersing
57
58
59 336 phase melts [2, 48]) or other macroscopic instabilities.

1 337 It is worth noting that the temperature ramp test does not evidence significant
2
3 338 differences between the samples because the thermal behaviour is mainly related to the
4
5
6 339 hydrogel characteristics.

9 340 **3.2 Electric conductivity**

11
12 341 Electric conductivity (κ) was investigated aiming at better understanding the
13
14 342 microstructural characteristics of emulsified bigels [1]. Fig. 5 shows the variation of
15
16
17 343 conductivity starting from E0 to E25. The reported results indicate a huge decrease in
18
19 344 electric conductivity correspondent to the increasing organogels addition to the starting
20
21
22 345 system. Since sample E0 is an O/W system, the gelled aqueous phase is continuous: this
23
24 346 allows the system to conduce well the electric current thanks to the ions naturally
25
26
27 347 present within the thermal water. When an oil phase is added to the system, no matter
28
29 348 its rheological characteristics, the electric conduction of the final material is, obviously,
30
31
32 349 reduced. This is because oil phases are natural electric insulants. Therefore, the
33
34 350 reduction in conductivity can be attributed to the isolating action of the organogel.
35
36
37 351 Going from sample E10 to E15, a further, stronger reduction in electric conductivity is
38
39 352 found, and then an unexpected increase in sample E20 is observed, followed by a
40
41
42 353 further decrease in E25. This trend seems to suggest that more complex changes than
43
44 354 phase inversion are occurring within the system. In fact, phase inversion (i.e. the
45
46 355 transition from O/W bigels to W/O bigels) should yield almost zero values of electrical
47
48
49 356 conductivity (being the organogel an insulant), whereas experimental results seem to
50
51
52 357 suggest a different spatial distribution of the phases, in such a way that the oil phase,
53
54 358 even though present in a larger amount, seems to affect the conductivity less.

55
56
57 359

1 360 **3.3 NMR-self diffusion results**

2
3
4 361 The NMR self-diffusion method can distinguish continuous and dispersed phases based
5
6
7 362 on the transport properties of the component molecules [24, 28]. Generally speaking,
8
9 363 from the oil and water apparent self-diffusion coefficients it is possible to distinguish
10
11 364 between oil-in-water (O/W), water-in-oil (W/O) or continuous type. In O/W emulsions
12
13 365 the oil self-diffusion coefficient, D^{oil} , is much lower than water self-diffusion one, D^w ,
14
15 366 in W/O emulsions $D^w \ll D^{oil}$, while in continuous phase $D^w \sim D^{oil}$ [24]. However,
16
17 367 solvation effects, incomplete segregation into domains or other inhomogeneities can
18
19 368 affect the diffusion. In the special case of bigels is reasonable to believe that similar
20
21 369 behaviors can be observed for W/O and O/W or bicontinuous bigel emulsions. In these
22
23 370 conditions the diffusion can be written
24
25
26
27

28
29
30 371
$$D^w = f_i^n D_i^w + f_b^n D_b^w \quad (3)$$

31
32
33 372 where D_b^w is the diffusion of the bonded water molecules, while D_i^w , is the diffusion
34
35 373 due to the inhomogeneities and will affect in proportion the fraction of molecules in the
36
37 374 same framework f_i^n . Comparing with a multiple emulsion the water self-diffusion
38
39 375 coefficient coming from the inhomogeneities correspond to the inner phase. Eq. 3 was
40
41 376 used to analyse the data in terms of weighted D_b^w and D_i^w coefficients. Fig. 6 reports
42
43 377 both water apparent self-diffusion coefficients and the relative fraction of molecules for
44
45 378 all samples studied.
46
47
48
49
50

51
52 379 The black colour in Fig. 6 evidences the fraction of bonded water molecules with the
53
54 380 corresponding diffusion coefficient. In sample E15, a strong decrease of the D_b^w
55
56 381 coefficient can be observed, D_b^w is also the main diffusion coefficient of the system,
57
58
59
60

1 382 since the fraction of the inhomogeneities is very low at this organogel concentration.
2
3
4 383 Increasing the organogel content the f_i^n grows and it may be related to domains of a
5
6 384 secondary emulsion, further investigations are needed on this point.
7
8
9
10 385 Fig. 7 shows the oil self-diffusion coefficients as a function of organogel concentration,
11
12 386 these data crossed with the previous ones provide a reasonable picture of the evolution
13
14 387 of the system. Therefore, systems can be considered as organogel-in-hydrogel (O/W) at
15
16 388 low fraction of organogels added to E0 (up to E10), since D^{oil} , is much lower than water
17
18 389 self-diffusion, D_b^w . D_i^w has the same order of magnitude than D^{oil} for sample E20 and
19
20
21
22 390 this can be related to a bicontinuous phase. However, E15 shows an inversion between
23
24 391 D_b^w and D_i^w that could suggest a structural change potentially occurring when the
25
26
27 392 highest fractions of organogel are added to the starting system; these structural changes
28
29 393 could be attributed to the formation of a complex system, even including a phase
30
31 394 inversion. Nevertheless, as already discussed in paragraph 3.2, sample E25 is still
32
33 395 characterised by a conductivity value different from zero, suggesting that the system is
34
35 396 more complex than a simple W/O one. In the light of this, contrast phase microscopy
36
37 397 was also carried out to better understand the real microstructure of the system.
38
39
40
41
42

43 398 **3.4 Contrast phase microscopy**

44
45
46 399 With the aim of confirming the results obtained by NMR-self diffusion indicating a
47
48 400 change in structural disposition of both phases forming bigel system, a further
49
50 401 investigation of the mutual disposition of oil and aqueous phase was carried out with
51
52 402 contrast phase optical microscopy. Fig. 8 shows the results for the investigated samples:
53
54 403 E0 shows the typical microstructure of an O/W emulsion, and oil droplets within an
55
56 404 aqueous phase can be easily recognised. Starting from sample E5, where organogel was
57
58
59
60
61
62
63
64
65

1 405 added in the lower fraction within the oil phase, a more complex microstructure
2
3 406 becomes evident.
4
5

6
7 407 As a result of all tests carried out on these materials, it was speculated that the addition
8
9 408 of the highest fractions of organogel mixed the starting emulgel leads to the formation
10
11 409 of a complex matrix-in-matrix system where an organogel is distributed within a
12
13 410 hydrogel containing, in turn, droplets of unstructured oil. This system is similar to that
14
15 411 shown by Di Michele et al. [49].
16
17
18

19 412 These complex structures, different from a simple system where one phase is dispersed
20
21 413 within another one, can explain the unexpected experimental results obtained by using
22
23 414 the different analytical techniques.
24
25
26

27
28 415
29
30

31 416 **4. CONCLUSIONS** 32 33

34 417 The rheological and microstructural characteristics of cosmetic bigels, i.e two-phase
35
36 418 systems where both phases are structured, [5, 7, 8] were investigated. Starting from a
37
38 419 cosmetic cream basis, bigels were produced adding increasing fractions of a
39
40 420 monoglycerides of fatty acids/olive oil organogel. A microstructural investigation was
41
42 421 carried out on bigel samples using techniques already adopted in this area, such as
43
44 422 rheological dynamic tests [7] and microscopy [14, 16]. Moreover, material
45
46 423 microstructure and the relative position of aqueous and oily phases were investigated by
47
48 424 using other experimental procedures, commonly adopted for emulsion characterisation
49
50 425 [1, 24, 27] and, so far, not used in bigels analysis. Electrical conductivity was adopted
51
52 426 to study the potential change in spatial distribution of phases that could occur when
53
54
55
56
57
58
59

1 427 organogel content increases, whereas Nuclear Magnetic Resonance (NMR), being a
2
3 428 powerful non-invasive technique, was used to further analyse the bigel microstructure.
4
5
6 429 It is worth noticing that owing to the lack of previous works on bigels, carried out by
7
8
9 430 using these techniques, more difficulties were found in data analysis and discussion.
10
11
12 431 Rheology was also used to investigate the bigel stability with dynamic temperature
13
14 432 ramp tests [2] evidencing for all samples satisfying results probably because of the
15
16 433 starch hydrogel characteristics.
17
18
19 434 The increasing addition of organogel fractions to the base emulsion caused the expected
20
21 435 growth of samples consistency [34] (indirectly evaluated with parameter *A* of the weak
22
23 436 gel model for the first time) up to a specific amount of organogel, correspondent to
24
25 437 sample E10, after which a minimum value and a following new increase was found.
26
27
28 438 This unexpected result was further investigated with other techniques and NMR self-
29
30 439 diffusion data were discussed on the basis of results obtained for emulsions, owing to
31
32 440 the lack of previous data on bigels, suggesting a transition from an O/W system to a
33
34 441 more complex spatial arrangement of the phases, similar to that observed for
35
36 442 bicontinuous emulsions [28]. For the first time the NMR echo-decay analysis was
37
38 443 adapted to bigel systems by using a bimodal exponential function.
39
40
41 444 Microscopy and electric conductivity seem to confirm this evidence suggesting the
42
43 445 formation of a complex matrix-in-matrix system, which could be considered, probably,
44
45 446 as a bicontinuous bigel at the highest fractions of organogel.
46
47
48 447 These results evidence that the addition of a structured oil phase to an existing O/W
49
50 448 system can significantly modify the microstructure and, therefore, the macroscopic
51
52
53
54
55
56
57
58
59
60
61
62
63
64
65

1 449 properties. Probably, owing to the high consistency of both materials, it is very difficult
2
3
4 450 to disperse the organogel within the existing aqueous phase. Therefore, a more complex
5
6 451 material, where both phases seem entrapped one inside the other, is obtained. In this
7
8 452 way, properties intermediate between those of O/W and W/O bigels can be obtained
9
10 453 and, probably, tuned, depending on the ratio between the phases.

11
12
13
14 454 Since bigel structure is a result of an out-of-equilibrium process is consequently very
15
16 455 hard to be predicted. In conclusion several insight to understand the bigel structure were
17
18
19 456 given.

20
21
22 457 Nevertheless, further investigations should be carried out on simpler model bigels, by
23
24 458 changing also the amount of hydrogel, to confirm the obtained results and to model the
25
26
27 459 rheological properties of the bigel as function of both phases content.

Ingredients	Amount (w/w%)
<i>Aqueous phase</i>	
Aqua (Sulphurous hyperthermal water)	64.08
Glycerin (Vegetable Glycerol)	2.5
Algae (Glyceric extract of algal microflora 1:1 in Sodium Benzoate 0.3%, Sodium dehydroacetate 0.3%, phenoxyethanol 0.7%, pH 4)	2.5
Potato starch modified (natural rheological modifier)	0.5
Sodium Ascorbyl Phosphate (anti-oxidant)	0.5
Phenoxyethanol (preservative)	0.7
Glycerin and Ethyl Lauroyl Arginate HCl (Aminat G) (preservative)	0.5
Tetrasodium Glutamate Diacetate (chelating agent GLDA) (Natural Chelating agent)	0.1
<i>Oil phase</i>	
Acemulgol Lam "V" (Potassium Palmitoyl Hydrolyzed Wheat Protein, Glyceryl Stearate, Cetearyl Alcohol) (Vegetable emulsifier)	9
Tegosoft CT (caprylic/capric Triglyceride) (Ester)	3
Prunus Amygdalus Dulcis Oil	3
Olea Europea Oil (Extra virgin olive oil)	10
Cethyl Alcohol (co-emulsifier)	2
Tocopheryl Acetate (anti-oxidant)	1
Ascorbyl Palmitate (anti-oxidant)	0.01
Citrus Arantium Dulcis Oil (Orange essential oil)	0.4
Citrus Medica Limonum Peel Oil (Lemon essential oil)	0.2
Cymbopogon Nardus Oil (Citronella essential oil)	0.01

Table 1

Ingredients	Quantity (w/w%)
Myverol	15.56
Ascorbyl Palmitate	0.01
Algae	7.02
α -tocopherol	0.65
Extra Virgin Olive oil	76.76

Table 2

Sample	Aqueous phase (w/w%)	Oil phase (w/w%)
E0	71.38	28.62
E5	68.00	32.00
E10	65.50	34.50
E15	63.50	36.50
E20	58.60	41.40
E25	55.10	44.90
